# Exergy analysis of solid oxide fuel cell operating 

# on natural gas 

Kesavarapu Uma Sai Mahesh

A Thesis Submitted to Indian Institute of Technology Hyderabad In Partial Fulfillment of the Requirements for The Degree of Master of Technology

भारतीय प्रौद्योगिकी संस्थान हैदराबाद Indian Institute of Technology Hyderabad

Department of Chemical Engineering

## Declaration

I declare that this written submission represents my ideas in my own words, and where ideas or words of others have been included, I have adequately cited and referenced the original sources. I also declare that I have adhered to all principles of academic honesty and integrity and have not misrepresented or fabricated or falsified any idea/data/fact/source in my submission. I understand that any violation of the above will be a cause for disciplinary action by the Institute and can also evoke penal action from the sources that have thus not been properly cited, or from whom proper permission has not been taken when needed.

## Approval Sheet

This Thesis entitled Exergy analysis of solid oxide fuel cell operating on natural gas by Kesavarapu Uma Sai Mahesh is approved for the degree of Master of Technology from IIT Hyderabad

(Dr Vinod Janardhanan) Adviser Dept. of Chem Engg IITH

(Dr Praveen Meduri) Examiner
Dept. of Chem Engg
IITH

(Dr Satyavrata Samavedi) Examiner Dept. of Chem Engg

IITH

## Acknowledgements

It is great and immense pleasure that I have worked under the guidance of Dr. Vinod Janardhanan. I would like to express my sincere gratitude to my adviser Dr. Vinod Janardhanan for giving his guidance, assistance and suggestions throughout the project course. I felt really joyful to have a flexible advisor like him. Because of Dr. Vinod Janardhanan, an adept in fuel cell technology, I have improved my knowledge in the field of fuel cell technology.
I am also thankful to my thesis committee members Dr. Satyavrtaa Samavedi and Dr. Praveen Meduri for their valuable comments and suggestions.
I also thank my research group members ( Vivek, Prakash and Swetha ) for their support. I am very thankful to Mr. Prakash who helped me to understand the simulation better.

## Dedication

## To my parents and friends

#### Abstract

The fuel cell performance can be determined by various methods described in literature like impedence studies, cycle voltametry efficiency and exergy analysis etc,. In this work exergy analysis is implemented to study the performance of two types of fuel cells namely HT - PEMFC and SOFC. Exergy analysis can be used to determine not only the quantity of energy utilized but also the quality of the energy. Now a days exergy analysis is extensively used to determine the magnitude of energy loss and its location. In this work, exergy analysis is done on HT - PEMFC to identify the locations or equipments where loss of energy could be take place. This can be used to improve the overall performance of the system. In additional to the exergy analysis of HT-PEMFC, the performance of SOFC is also examined by exergy analysis. Assuming that all channels in a stack behave similarly, a single channel is simulated at different temperatures at different cell voltages and variable fuel composition. Also, SOFC is run at constant flow rate condition to validate the exergy analysis.

## Chapter 1

## Fuel cell fundamentals

### 1.1 History

Fuel cell technology was first developed in the year 1839 by Sir William Robert Grove [1]. Hydrogen and oxygen were mixed in an electrolyte to produce electricity. Earlier fuel cells were developed using platinum electrodes and sulphuric acid as the electrolyte. But, later sulphuric acid was replaced by other alkaline electrolytes due to its corrosive nature. The founder of the chemistry - physics, Friedrich Wilhelm Ostwald determined the interconnection of fuel cell components like electrodes, electrolyte, oxidizing and reducing agents [2]. In 1896, first fuel cell with practical applications was developed by William W. Jacques [3]. In 1900, Nernst used zirconium as solid electrolyte. In 1921, first molten carbonate fuel cell was built by Baur [4]. In 1959, fuel cell was used in 20 horsepower tractor successfully by Allis - Chalmers Manufacturing Company. In 1960s, fuel cells were used to produce electricity in NASA's Gemini and Apollo space crafts. In 1961, G.V.Elmore and H.A.Tanner developed a phosphoric acid fuel cell. In 1997, leading auto-mobile companies like Daimler - Benz and Toyota announced their project about fuel cell powered cars. In 2007, fuel cells were used for stationary backup power on commercial scale. In 2008, Daimler - Benz completed their projects about fuel cell powered cars [5]. Fuel cell technology was incorporated to run buses successfully. In 2009, micro - CHP units were sold in Japan. Fuel cell can be used in mobile phones and laptops. Motorola, Samsung, Sony have used fuel cells in telecommunication equipments [6]. Figure 1.1 represents the histroy of fuel cells [7].

Figure 1.1: History of fuel cells

### 1.2 Types of fuel cells

Fuel cells are divided primarily into categories based on their electrolyte type. Based on this classification, types of electro - chemical reactions take place in various fuel cells are different. These fuel cells differ each other in various parameters: the type of catalyst involved, the operating temperature range, the requirement of fuel and the type of application. There are mainly five types of fuel cells available as shown in the Table 1.1.

Table 1.1: Types of fuel cells

| S.No | Fuel cell type |
| :--- | :--- |
| 1. | Polymer electrolyte membrane fuel cell (PEMFC) |
| 2. | Phosphoric acid fuel cell (PAFC) |
| 3. | Alkaline fuel cell (AFC) |
| 4. | Molten carbonate fuel cell (MCFC) |
| 5. | Solid oxide fuel cell (SOFC) |

Table 1.2 shows a brief description of all types of fuel cells [8].

Table 1.2: Description of Fuel cell Types

| S.No | Fuel cell | Electrolyte | Charge carrier | Operating temperature | Catalyst | Fuel |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1. | PEMFC | Polymer membrane | $\mathrm{H}^{+}$ | $80^{\circ} \mathrm{C}$ | Platinum | $\mathrm{H}_{2}$, Methanol |
| 2. | PAFC | Liquid $\mathrm{H}_{3} \mathrm{PO}_{4}$ | $\mathrm{H}^{+}$ | $200^{\circ} \mathrm{C}$ | Platinum | $\mathrm{H}_{2}$ |
| 3. | AFC | Liquid KOH | $\mathrm{OH}^{-}$ | $60-220^{\circ} \mathrm{C}$ | Platinum | $\mathrm{H}_{2}$ |
| 4. | MCFC | Molten carbonate | $\mathrm{CO}_{3}^{2-}$ | $650^{\circ} \mathrm{C}$ | Nickel | $\mathrm{H}_{2}, \mathrm{CH}_{4}$ |
| 5. | SOFC | Ceramic | $\mathrm{O}^{2-}$ | $600-1000^{\circ} \mathrm{C}$ | Ceramic | $\mathrm{H}_{2}, \mathrm{CH}_{4}, \mathrm{CO}$ |

### 1.3 Advantages and Disadvantages of fuel cells

Fuel cell technology is a viable option to produce power due to its advantages over its counterparts like batteries and combustion engines. Energy density of fuel cells is much more than batteries. Table 1.3 shows advantages and disadvantages of fuel cell technology [9, 10].

Table 1.3: Advantages and Disadvantages of Fuel cells

| S.No | Advantages | Disadvantages |
| :--- | :--- | :--- |
| 1. | Simplicity in design | Expensive |
| 2. | Low emission | Fuel availability and storage |
| 3. | Silent operation | Limitation on operation temperature |
| 4. | High efficiency | Durability during start-up |

### 1.4 Solid Oxide Fuel Cell

When compared to different types of fuel cells, solid oxide fuel cell has advantages in terms of operating temperature, fuel choice and components involved. Solid oxide fuel cells are typically operated at the temperature range of $600^{\circ} \mathrm{C}-1000^{\circ} \mathrm{C}$. The electrolyte is in solid phase. So vigorous water management systems can be avoided. Due to high operating temperature, internal reforming of fuel can also be achieved within the cell which eliminate expensive set-up for reformation outside the cell. Also, high temperature operation allows to produce useful heat for co-generation and to construct hybrid systems. They are resistant to various impurities present in the fuel like carbon monoxide. Carbon monoxide can be used as fuel in this type of fuel cells. This made them to use natural gas, biogas and gases from coal as fuel. Table 1.4 shows advantages of Solid oxide fuel cell [10] .

Table 1.4: Advantages of Solid oxide fuel cell

| S.No | Advantages |
| :--- | :--- |
| 1. | High operation temperature |
| 2. | No electrolyte loss |
| 3. | No need of expensive catalysts |
| 4. | Ability to handle impurities |
| 5. | Internal reforming ability |
| 6. | High quality waste heat for co-generation |

Solid oxide fuel cells have disadvantages too. High temperature operation leads to slow start-up. It requires stringent durability requirements on materials. One of the key challenge in this type of fuel cells is development of low cost materials with high durability. For this reason development of lower - temperature SOFCs operating at $600^{\circ} \mathrm{C}$ to $700^{\circ} \mathrm{C}$ are being researched. This low temperature operation ensures fewer durability problems and less cost.

## Chapter 2

## Exergy

### 2.1 Concept of Exergy

It is essential to find out the efficiency of fuel cells either using thermodynamic efficiency or exergy efficiency. Methods based on the thermodynamics give the detailed information about the magnitude of losses within the cells. One of the methods which is based on the thermodynamics is concept of exergy. Efficiency based on the first law of thermodynamics gives information about quantity of the energy. On the other hand Exergy which is based on the second law of thermodynamics gives not only the quantity but also about quality of the energy.

Exergy concept was demonstrated by Gibbs in 1878. It was developed by Rant in 1957. Exergy is defined as the maximum amount of work obtained when the system comes to equilibrium while interacting with the environment. Environment is considered as large and uniform at the temperature $T_{0}$ and the pressure $P_{0}$. For the analysis of exergy the temperature and pressure of environment is considered to be constant at $25^{\circ} \mathrm{C}$ and at 1 atm .

When the system reaches the state of environment, there is still a chance to extract the work because of difference in the quantity of matter between the system and the environment even-though the system is at environmental state. A state which is reached when work is extracted as the matter is equilibrated with the environment is called as dead state.

### 2.1.1 Types of Exergy

There are several types of exergies and the total exergy is defined as

$$
\begin{equation*}
\mathbf{E}=\mathbf{E}_{\mathrm{ki}}+\mathbf{E}_{\mathrm{po}}+\mathbf{E}_{\mathrm{ph}}+\mathbf{E}_{\mathrm{ch}} . \tag{2.1}
\end{equation*}
$$

Where $\mathbf{E}_{\mathrm{ki}}, \mathbf{E}_{\mathrm{po}}, \mathbf{E}_{\mathrm{ph}}$ and $\mathbf{E}_{\mathrm{ch}}$ are kinetic, potential, physical and chemical exergies respectively.
Exergy of a system is given by

$$
\begin{equation*}
\mathbf{E}=\left(\mathrm{E}-\mathrm{U}_{0}\right)+\mathrm{P}_{0}\left(\mathrm{~V}-\mathrm{V}_{0}\right)-\mathrm{T}_{0}\left(\mathrm{~S}-\mathrm{S}_{0}\right) \tag{2.2}
\end{equation*}
$$

Where $\mathrm{E}(=\mathrm{U}+\mathrm{KE}+\mathrm{PE}), \mathrm{V}$ and S are energy, volume and entropy of the system respectively.

The specific exergy on a unit mass basis, e, is given by

$$
\begin{equation*}
\mathbf{e}=\left(\mathrm{e}-\mathrm{u}_{0}\right)+\mathrm{p}_{0}\left(\mathrm{v}-\mathrm{v}_{0}\right)-\mathrm{T}_{0}\left(\mathrm{~s}-\mathrm{s}_{0}\right) . \tag{2.3}
\end{equation*}
$$

Where e, v and s are the specific energy, volume and entropy of the system respectively. $\mathrm{u}_{0}, \mathrm{v}_{0}$ and $\mathrm{s}_{0}$ are evaluated at the dead state. With $e=\mathrm{u}+\frac{\mathrm{V}^{2}}{2}+\mathrm{gz}$,

$$
\begin{equation*}
e=\left[\left(\mathrm{u}+\frac{\mathrm{V}^{2}}{2}+\mathrm{gz}\right)-\mathrm{u}_{0}\right]+\mathrm{p}_{\mathrm{o}}\left(\mathrm{v}-\mathrm{v}_{0}\right)-\mathrm{T}_{0}\left(\mathrm{~s}-\mathrm{s}_{0}\right) \tag{2.4}
\end{equation*}
$$

. The above equation can be rewrite as

$$
\begin{equation*}
e=\left(\mathrm{u}-\mathrm{u}_{0}\right)+\mathrm{p}_{0}\left(\mathrm{v}-\mathrm{v}_{0}\right)-\mathrm{T}_{0}\left(\mathrm{~s}-\mathrm{s}_{0}\right)+\frac{\mathrm{V}^{2}}{2}+\mathrm{gz} \tag{2.5}
\end{equation*}
$$

In gerenal kinetic and potential exergies are omitted and physical and chemical exergies are considered for the calculations.

The change in exergy between two states is given by

$$
\begin{equation*}
\mathbf{E}_{2}-\mathbf{E}_{1}=\left(\mathrm{E}_{2}-\mathrm{E}_{1}\right)+\mathrm{p}_{0}\left(\mathrm{~V}_{2}-\mathrm{V}_{1}\right)-\mathrm{T}_{0}\left(\mathrm{~S}_{2}-\mathrm{S}_{1}\right) . \tag{2.6}
\end{equation*}
$$

### 2.2 Physical exergy

Physical exergy is defined as the maximum work is produced when the systme is brought from initial state $(T, P)$ to the environmental state $\left(\mathrm{T}_{0}, \mathrm{P}_{0}\right)$. The processes that are considered to be involved in the physical exergy are physical processes involves only thermal interactions with the environment.

### 2.2.1 Closed System Exergy balance

In a closed system, transfer of energy between system and the environment occurs without exchanging the matter. The exergy balance involves formation of energy and entropy across the boundary.

The energy and entropy balances are given by

$$
\begin{gather*}
\mathrm{E}_{2}-\mathrm{E}_{1}=\int_{1}^{2} \delta \mathrm{Q}-\mathrm{W},  \tag{2.7}\\
\mathrm{~S}_{2}-\mathrm{S}_{1}=\int_{1}^{2}\left(\frac{\delta \mathrm{Q}}{\mathrm{~T}}\right)+\sigma . \tag{2.8}
\end{gather*}
$$

Where W and Q represent work and heat transfers between the system and the surroundings. $\mathrm{T}, \delta \mathrm{Q}$ and $\sigma$ represent temperature of the system, amount of heat received and entropy generation.

Exergy balance for closed system is given by

$$
\begin{equation*}
\left(\mathrm{E}_{2}-\mathrm{E}_{1}\right)-\mathrm{T}_{0}\left(\mathrm{~S}_{2}-\mathrm{S}_{1}\right)=\int_{1}^{2} \delta \mathrm{Q}-\mathrm{T}_{0} \int_{1}^{2}\left(\frac{\delta \mathrm{Q}}{\mathrm{~T}}\right)-\mathrm{W}-\mathrm{T}_{0} \sigma \tag{2.9}
\end{equation*}
$$

Introducing Eq.2.6 on the left side, we can get

$$
\begin{equation*}
\left(\mathbf{E}_{2}-\mathbf{E}_{1}\right)-\mathrm{p}_{0}\left(\mathrm{~V}_{2}-\mathrm{V}_{1}\right)=\int_{1}^{2}\left(1-\frac{\mathrm{T}_{0}}{\mathrm{~T}}\right) \delta \mathrm{Q}-\mathrm{W}-\mathrm{T}_{0} \sigma \tag{2.10}
\end{equation*}
$$

$$
\begin{equation*}
\underbrace{\mathbf{E}_{2}-\mathbf{E}_{1}}_{\text {amount of exergy }}=\underbrace{\int_{1}^{2}\left(1-\frac{\mathrm{T}_{0}}{\mathrm{~T}}\right) \delta \mathrm{Q}}_{\text {exergy related to heat }}-\underbrace{\mathrm{W}-\mathrm{p}_{0}\left(\mathrm{~V}_{2}-\mathrm{V}_{1}\right)}_{\text {exergy related to work }}-\underbrace{\mathrm{T}_{0} \sigma .}_{\text {exergy destruction }} \tag{2.11}
\end{equation*}
$$

In the rate form, it is
$\underbrace{\frac{d \mathbf{E}}{d t}}_{\text {rate of change of exergy }}=\underbrace{\sum_{\mathrm{j}}\left(1-\frac{\mathrm{T}_{0}}{\mathrm{~T}}\right) \dot{\mathrm{Q}}_{\mathbf{j}}}_{\text {rate of change of exergy due to heat transfer }}-\underbrace{\left(\dot{\mathrm{W}}-\mathrm{p} \frac{\mathrm{dV}}{\mathrm{dt}}\right)}_{\text {rate of change of volume of system }}-\underbrace{\dot{\mathbf{E}}_{d} .}_{\text {rate of exergy destruction }}$

### 2.2.2 Open system exergy balance

Open system is defined as transfer of not only energy but also the matter between system and the environment.

Specific flow exergy is given by

$$
\begin{equation*}
\mathrm{e}_{\mathrm{f}}=\mathrm{h}-\mathrm{h}_{0}-\mathrm{T}_{0}\left(\mathrm{~s}-\mathrm{s}_{0}\right)+\frac{\mathrm{V}^{2}}{2}+\mathrm{gz} \tag{2.13}
\end{equation*}
$$

Where $h$ and s represent the specific enthalpy and entropy of the system respectively. $\mathrm{h}_{0}$ and $\mathrm{s}_{0}$ are evaluated at the dead state. f stands for flow.

Exergy balance for control volume is

$$
\begin{equation*}
\underbrace{\frac{d \mathbf{E}}{d t}}_{\text {rate of exergy change }}=\underbrace{\sum_{\mathrm{j}}\left(1-\frac{\mathrm{T}_{0}}{\mathrm{~T}_{\mathrm{j}}}\right) \dot{\mathrm{Q}}_{\mathrm{j}}-\left(\dot{\mathrm{W}}-\mathrm{p}_{0} \frac{d \mathrm{~V}}{d t}\right)+\sum_{\mathrm{i}} \dot{\mathrm{~m}}_{\mathrm{i}} \mathrm{e}_{\mathrm{fi}}-\sum_{\mathrm{e}} \dot{\mathrm{~m}}_{\mathrm{e}} \mathrm{e}_{\mathrm{ef}}}_{\text {rate of exergy transfer }}-\underbrace{\dot{\mathbf{E}}_{d}}_{\text {rate of exergy destruction }} \tag{2.14}
\end{equation*}
$$

Where i, e, $\dot{m}$ and $j$ denote inlet, exit, mass flow rate and location on the boundary respectively. Steady - state form is

$$
\begin{equation*}
0=\sum_{\mathrm{j}}\left(1-\frac{\mathrm{T}_{0}}{\mathrm{~T}_{\mathrm{j}}}\right) \dot{\mathrm{Q}}_{\mathrm{j}}-\dot{\mathrm{W}}+\sum_{\mathrm{i}} \dot{\mathrm{~m}}_{\mathrm{i}} \mathrm{e}_{\mathrm{fi}}-\sum_{\mathrm{e}} \dot{\mathrm{~m}}_{\mathrm{e}} \mathrm{e}_{\mathrm{fe}}-\dot{\mathbf{E}}_{\mathrm{d}} \tag{2.15}
\end{equation*}
$$

For one inlet and one outlet, it becomes

$$
\begin{equation*}
0=\sum_{\mathrm{j}}\left(1-\frac{\mathrm{T}_{0}}{\mathrm{~T}_{\mathrm{j}}}\right) \dot{\mathrm{Q}}_{\mathrm{j}}-\dot{\mathrm{W}}+\dot{\mathrm{m}}\left(\mathrm{e}_{\mathrm{f} 1}-\mathrm{e}_{\mathrm{f} 2}\right)-\dot{\mathbf{E}}_{\mathrm{d}} \tag{2.16}
\end{equation*}
$$

Where,

$$
\begin{equation*}
\mathrm{e}_{\mathrm{f} 1}-\mathrm{e}_{\mathrm{f} 2}=\left(\mathrm{h}_{1}-\mathrm{h}_{2}\right)-\mathrm{T}_{0}\left(\mathrm{~s}_{1}-\mathrm{s}_{2}\right)+\frac{\mathrm{V}_{1}^{2}-\mathrm{V}_{2}^{2}}{2}+\mathrm{g}\left(\mathrm{z}_{1}-\mathrm{z}_{2}\right) \tag{2.17}
\end{equation*}
$$

If the velocities at the both ends are almost same and there is no elevation then

$$
\begin{equation*}
\mathrm{e}_{\mathrm{f} 1}-\mathrm{e}_{\mathrm{f} 2}=\left(\mathrm{h}_{1}-\mathrm{h}_{2}\right)-\mathrm{T}_{0}\left(\mathrm{~s}_{1}-\mathrm{s}_{2}\right), \tag{2.18}
\end{equation*}
$$

or generally at one location

$$
\begin{equation*}
\mathbf{E}_{\mathrm{ph}}=\left(\mathrm{h}-\mathrm{h}_{0}\right)-\mathrm{T}_{0}\left(\mathrm{~s}-\mathrm{s}_{0}\right) \tag{2.19}
\end{equation*}
$$

The above equation is treated as physical exergy.
For Ideal gaseous mixture,
the enthalpy depends only on the temperature as follows

$$
\begin{equation*}
\mathrm{h}-\mathrm{h}_{0}=\int_{\mathrm{T}_{0}}^{\mathrm{T}} \mathrm{c}_{\mathrm{p}} \mathrm{dT} . \tag{2.20}
\end{equation*}
$$

The entropy change is given by

$$
\begin{align*}
s-s_{0} & =\int_{T_{0}}^{T} c_{p} \frac{d T}{T}-R \int_{p_{0}}^{p} \frac{d p}{p}  \tag{2.21}\\
s-s_{0} & =\int_{T_{0}}^{T} c_{p} \frac{d T}{T}-R \ln \frac{p}{p_{0}} \tag{2.22}
\end{align*}
$$

For constant values of $c_{p}$,

$$
\begin{equation*}
\mathbf{E}_{\mathrm{ph}}=\mathrm{c}_{\mathrm{p}}\left(\mathrm{~T}-\mathrm{T}_{0}\right)-\mathrm{T}_{0} \mathrm{c}_{\mathrm{p}} \ln \frac{\mathrm{~T}}{\mathrm{~T}_{0}}+\mathrm{RT}_{0} \ln \frac{\mathrm{p}}{\mathrm{p}_{0}} . \tag{2.23}
\end{equation*}
$$

Where $c_{p}$ represents specific heat capacity. $T$ and $p$ represent temperature and pressure of the system. $\mathrm{T}_{0}$ and $\mathrm{p}_{0}$ represents standard temperature and pressure respectively.

### 2.3 Chemical Exergy

Chemical exergy is defined as the maximum amount of work is produced when the system is brought from the environmental state to the dead state. The chemical exeryg is related to the departure of the chemical composition of a system from that of the environment. To determine the chemical exergy of species present in the system we need to define the proper reference environment. Generally this reference environment is taken as the atmosphere, the oceans and the earth's crust at the temperature $\mathrm{T}_{0}$ and pressure $\mathrm{P}_{0}$.

### 2.3.1 Reference Components from Air

The main components of air are $\mathrm{O}_{2}, \mathrm{~N}_{2}, \mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$, at 298.15 K and 1 atm. Table 2.1 shows partial pressure of these components [11].

Table 2.1: Partial Pressures of components

| Component | Partial pressure $(\mathrm{kPa})$ |
| :--- | :--- |
| $\mathrm{N}_{2}$ | 75.78 |
| $\mathrm{O}_{2}$ | 20.39 |
| $\mathrm{CO}_{2}$ | 0.0335 |
| $\mathrm{H}_{2} \mathrm{O}$ | 2.2 |

### 2.3.2 Chemical Exergy of mixture

The chemical exergy of the mixture can be calculated once the chemical exergy of all the substances present in the process is obtained. Specific chemical exergy depends on the streams composition,
for calculation of chemical exergy of the stream we need the information about the specific chemical exergy of the substances and their molar fractions.

For gas mixtures and ideal liquid solutions the formula is given by [12],

$$
\begin{equation*}
\mathbf{E}_{\mathrm{ch}}=\sum_{\mathrm{i}} \mathrm{x}_{\mathrm{i}} \mathrm{e}_{\mathrm{ch}, \mathrm{i}}+\mathrm{RT}_{0} \sum_{\mathrm{i}} \mathrm{x}_{\mathrm{i}} \ln \mathrm{x}_{\mathrm{i}} . \tag{2.24}
\end{equation*}
$$

where $e_{c h, i}, x_{i}$ are specific chemical exergy of $i^{\text {th }}$ substance and mole fraction of substance in the mixture respectively.

The Standard Chemical Exergy Values of components are listed in Table 2.2 [13].
Table 2.2: Standard Chemical exergy values

| Component | Standard Chemical exergy, $\mathrm{e}_{\mathrm{ch}, \mathrm{i}}(\mathrm{kJ} / \mathrm{mol})$ |
| :--- | :--- |
| $\mathrm{CH}_{4}$ | 831.2 |
| $\mathrm{H}_{2} \mathrm{O}$ | 9.5 |
| $\mathrm{H}_{2}$ | 236.09 |
| $\mathrm{O}_{2}$ | 3.97 |
| $\mathrm{~N}_{2}$ | 0.72 |
| $\mathrm{CO}_{2}$ | 19.48 |
| CO | 274.71 |

### 2.4 Exergy Efficiency of common components

### 2.4.1 Heat Exchanger without Mixing

Figure 2.1: Counter flow heat exchanger

Figure 2.1 represents a counter flow heat exchanger [14]. The mass flow rate of hot stream is $\dot{\mathrm{m}}_{\mathrm{h}}$ and that of cold stream is $\dot{m}_{c}$. Assume that the heat exchanger is at steady state with no heat transfer with the environment. The rate of change of exergy balance is given as

$$
\begin{equation*}
0=\sum_{\mathrm{j}}\left(1-\frac{T_{0}}{T}\right) \dot{\mathrm{Q}}_{\mathrm{j}}^{0}-\dot{W}^{0}+\left(\dot{\mathrm{m}}_{\mathrm{h}} \mathrm{e}_{\mathrm{f} 1}+\dot{\mathrm{m}}_{\mathrm{c}} \mathrm{e}_{\mathrm{f} 3}\right)-\left(\dot{\mathrm{m}}_{\mathrm{h}} \mathrm{e}_{\mathrm{f} 2}+\dot{\mathrm{m}}_{\mathrm{c}} \mathrm{e}_{\mathrm{f} 4}\right)-\dot{\mathbf{E}}_{\mathrm{d}} \tag{2.25}
\end{equation*}
$$

$$
\begin{equation*}
\dot{\mathrm{m}}_{\mathrm{h}}\left(\mathrm{e}_{\mathrm{f} 1}-\mathrm{e}_{\mathrm{f} 2}\right)=\dot{\mathrm{m}}_{\mathrm{c}}\left(\mathrm{e}_{\mathrm{f} 4}-\mathrm{e}_{\mathrm{f} 3}\right)+\dot{\mathbf{E}}_{\mathrm{d}} . \tag{2.26}
\end{equation*}
$$

The exergy efficiency of heat exchanger is given as

$$
\begin{equation*}
\varepsilon=\frac{\dot{\mathrm{m}}_{\mathrm{c}}\left(\mathrm{e}_{\mathrm{f} 4}-\mathrm{e}_{\mathrm{f} 3}\right)}{\dot{\mathrm{m}}_{\mathrm{h}}\left(\mathrm{e}_{\mathrm{f} 1}-\mathrm{e}_{\mathrm{f} 2}\right)} . \tag{2.27}
\end{equation*}
$$

### 2.4.2 Direct contact heat exchanger

Figure 2.2: Direct contact heat exchanger

Figure 2.2 represents a mixer with two streams flowing into the system and after mixing one stream leaving the system [14]. The exergy balance is given as

$$
\begin{equation*}
0=\sum_{\mathrm{j}}\left(1-\frac{T_{0}}{T}\right)^{0} \dot{\mathrm{Q}}_{\mathrm{j}}-\dot{W}^{\neq}+\dot{\mathrm{m}}_{1} \mathrm{e}_{\mathrm{f} 1}-\dot{\mathrm{m}}_{3} \mathrm{e}_{\mathrm{f} 3}-\dot{\mathbf{E}}_{\mathrm{d}} \tag{2.28}
\end{equation*}
$$

and

$$
\begin{equation*}
\dot{\mathrm{m}}_{3}=\dot{\mathrm{m}}_{1}+\dot{\mathrm{m}}_{2} \tag{2.29}
\end{equation*}
$$

Therefore the equation is reduced to

$$
\begin{equation*}
\dot{\mathrm{m}}_{1}\left(\mathrm{e}_{\mathrm{f} 1}-\mathrm{e}_{\mathrm{f} 3}\right)=\dot{\mathrm{m}}_{2}\left(\mathrm{e}_{\mathrm{f} 3}-\mathrm{e}_{\mathrm{f} 2}\right)+\dot{\mathbf{E}}_{\mathrm{d}} . \tag{2.30}
\end{equation*}
$$

The exergy efficiency is given as

$$
\begin{equation*}
\varepsilon=\frac{\dot{\mathrm{m}}_{2}\left(\mathrm{e}_{\mathrm{f} 3}-\mathrm{e}_{\mathrm{f} 2}\right)}{\dot{\mathrm{m}}_{1}\left(\mathrm{e}_{\mathrm{f} 1}-\mathrm{e}_{\mathrm{f} 3}\right)} . \tag{2.31}
\end{equation*}
$$

## Chapter 3

## HT - PEMFC

### 3.1 Polymer Electrolyte Membrane Fuel cell

Polymer Electrolyte Membrane Fuel cells(PEMFC) are operable in the temperature range from $80^{\circ} \mathrm{C}$ to $200^{\circ} \mathrm{C}$. These fuel cells mainly use $\mathrm{H}_{2}$ as fuel. These cells are best for transport, mobile auxiliary and combined heat and power (CHP) applications. These are first choice for transport industry because of their rapid start-up, high power density and efficiency. There are two types of PEMFC's. Low Temperature Polymer Electrolyte Membrane Fuel cells(LT-PEMFC) and High Temperature Polymer Electrolyte Membrane Fuel cells(HT-PEMFC).

Low temperature Polymer Electrolyte Membrane Fuel cells are operated at $80^{\circ} \mathrm{C}$. They suffer from number of disadvantages mainly low tolerance to impurities and water management. By switching to high temperature Polymer Electrolyte Membrane Fuel cells the above mentioned difficulties can be mitigated.

### 3.2 High Temperature Polymer Electrolyte Membrane Fuel Cells

HTPEMFC are operable upto $200^{\circ} \mathrm{C}$ with improved kinetics which lead to improved performance compared to LTPEMFC. Table 3.1 provides advantages and disadvantages of HTPEMFC [15, 16].

Table 3.1: Advantages and Disadvantages of PEMFC

| S.NO. | Advantages | Disadvantages |
| :--- | :--- | :--- |
| 1. | Improved reaction kinetics | Dehydration of membrane |
| 2. | CO tolerance | Increased start-up time |
| 3. | Heat and water management | Acid leaching |
| 4. | Use of alternative catalysts | Durability |

### 3.3 Model description

In this work, a process model is taken from the report of A. Arsalis et al [17]. The process flow diagram is shown in the Fig. 3.1. The desulfurized natural gas is sent to the mixer. Water is heated in the steam generator to become superheated steam. The superheated steam is also sent to the mixer. After mixer, the mixture is fed to the tube side of the SMR reactor. The shell side of the SMR reactor is occupied by the flue gases from the catalytic combustor. In catalytic combustor, air is fed along with the depleted fuel from the fuel cell to produce the flue gases at high temperature. A side stream of natural gas is bypassed from the natural gas inlet to meet the demand for combustor.

Figure 3.1: Layout of CHP system

In the SMR reactor, reforming reaction occurs and carbon monoxide and hydrogen are formed. To reduce the carbon monoxide content that is going into the fuel cell, the reformate gas mixture is sent to the WGS reactor along with water. The carbon monoxide is converted into the carbon dioxide in the WGS reactor.

The reformate fuel enters the fuel cell anode. Air enters at the cathode part of the cell. Electrochemical reaction takes place and the huge amount of heat is released along with the product. This heat is used in various heat exchangers and for space heating.

The following reactions are occurring at the various equipments.
SMR reactor:

$$
\begin{equation*}
\mathrm{CH}_{4}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{CO}+3 \mathrm{H}_{2}, \tag{3.1}
\end{equation*}
$$

$$
\begin{gather*}
\mathrm{CO}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{CO}_{2}+\mathrm{H}_{2},  \tag{3.2}\\
\mathrm{CH}_{4}+2 \mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{CO}_{2}+4 \mathrm{H}_{2} . \tag{3.3}
\end{gather*}
$$

WGS reactor:

$$
\begin{equation*}
\mathrm{CO}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{CO}_{2}+\mathrm{H}_{2} \tag{3.4}
\end{equation*}
$$

Combustor:

$$
\begin{gather*}
\mathrm{H}_{2}+0.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow \mathrm{H}_{2} \mathrm{O}+0.5(3.76) \mathrm{N}_{2},  \tag{3.5}\\
\mathrm{CH}_{4}+2\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+7.52 \mathrm{~N}_{2} . \tag{3.6}
\end{gather*}
$$

Fuel cell stack:

$$
\begin{equation*}
\mathrm{H}_{2}+0.5 \mathrm{O}_{2} \rightarrow \mathrm{H}_{2} \mathrm{O} \tag{3.7}
\end{equation*}
$$

### 3.4 Exergy analysis

The inputs to the system are natural gas, water and air at various points. The input temperature and flow rates are shown in the Table 3.2.

Table 3.2: Input flowrates of substances

| S.No. | Component | Temperature (K) | flowrate $(\mathrm{Kg} / \mathrm{s})$ |
| :--- | :--- | :--- | :--- |
| 1. | Natural gas | 288 | $7.31 \mathrm{E}-05$ |
| 2. | Water | 293 | $1.10 \mathrm{E}-02$ |
| 3. | Air | 288 | $6.50 \mathrm{E}-03$ |

The exergy analysis of the equipemnts involves the calculation of the enthalpy and entropy at the inlet and outlet conditions which depends on temperature and pressure. By knowing the temperature and pressure at the inlet and outlet of the each and every equipment we can calculate physical exergy (Eq. 2.12) and chemical exergy (Eq. 2.17) depending on the type of process involved in the equipment.

The types of heat exchangers involved in the system are shown in Table 3.3
Table 3.3: Heat exchangers involved in the CHP System

| S.No | Equipment Name | Equipment Type |
| :--- | :--- | :--- |
| 1. | Natual gas preheater | Indirect contact heat exchanger |
| 2. | Steam generator | Indirect contact heat exchanger |
| 3. | SMR/WGS Cooler | Indirect contact heat exchanger |
| 4. | WGS/HT - PEMFC Cooler | Indirect contact heat exchanger |
| 5. | $1^{\text {st }}$ cogeneration | Indirect contact heat exchanger |
| 6. | $2^{\text {nd }}$ cogeneration | Indirect contact heat exchanger |
| 7. | $3^{\text {rd }}$ cogeneration | Indirect contact heat exchanger |
| 8. | Mixer | Direct contact heat exchanger |

The remaining equipments are shown in Table 3.4.

Table 3.4: Equipments involved chemical reactions in CHP system

| S.No | Equipment Name |

From the NASA Polynomials enthalpy and entropy values are calculated and total exergy is calculated at both ends by combining physical and chemical exergies. The exergy efficiency is calculated based on the Eq. 2.20 for indirect contact heat exchanger. Direct contact heat exchanger exergy efficiency is calculated based on the Eq. 2.20 and Eq. 2.24. The exergy analysis of various heat exchangers in the system is shown in Table 3.7 and exergy analysis of equipments involving chemical reactions is shown in Table 3.8.

## Chapter 4

## SOFC Model

The SOFC model considered here is planar configuration. The code consists of following files to execute the code: cloud.xml, chem.inp, ch4.xml, electrochem.xml and therm.dat. Assuming that all channels in a stack behave similarly, a single channel is simulated. A mixture of methane and water is considered as the fuel. In the SOFC, the following overall reaction is taken place.

$$
\begin{equation*}
\mathrm{CH}_{4}+2 \mathrm{O}_{2} \rightarrow 2 \mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2} \tag{4.1}
\end{equation*}
$$

The model is simulated at different mole fractions of $\mathrm{CH}_{4}$ by varying operating voltage. The model is simulated at constant flow rate condition. In constant flow rate condition, a constant amount of fuel is supplied to the cell regardless of how much it actually needs at given current density.

The geometrical model considered in this work is single channel. The species mass fractions $Y_{\mathrm{k}}$ in the flow channels are calculated from [18]

$$
\begin{equation*}
\frac{\partial\left(\rho \mathrm{Y}_{\mathrm{k}}\right)}{\partial \mathrm{t}}+\frac{\partial\left(\rho \mathrm{u} \mathrm{Y}_{\mathrm{k}}\right)}{\partial \mathrm{x}}=\frac{\mathrm{P}_{\mathrm{e}}}{\mathrm{~A}_{\mathrm{c}}} \mathrm{j}_{\mathrm{k}} ; \mathrm{k}=1 \ldots . \mathrm{N}_{\mathrm{g}} . \tag{4.2}
\end{equation*}
$$

And the velocity is calculated from

$$
\begin{equation*}
\frac{\partial(\rho \mathrm{u})}{\partial \mathrm{t}}+\frac{\partial(\rho \mathrm{uu})}{\partial \mathrm{x}}=\mathrm{u} \sum_{\mathrm{k}=1}^{\mathrm{N}_{\mathrm{g}}} \frac{\mathrm{P}_{\mathrm{e}}}{\mathrm{~A}_{\mathrm{c}}} \mathrm{j}_{\mathrm{k}} \tag{4.3}
\end{equation*}
$$

The pressure in the channel is assumed to be constant at atmospheric. The density then follows from the ideal gas equation is

$$
\begin{equation*}
\rho=\frac{\mathrm{p} \overline{\mathrm{M}}}{\mathrm{RT}} \tag{4.4}
\end{equation*}
$$

In the above equations $\mathrm{j}_{\mathrm{k}}$ is the flux at the interface between the flow channel and the electrode, which is calculated using

$$
\begin{equation*}
\frac{\mathrm{j}_{\mathrm{k}}}{\mathrm{M}_{\mathrm{k}}}=\sum_{\mathrm{k}=1}^{\mathrm{N}_{\mathrm{g}}} \mathrm{~d}_{\mathrm{kl}}^{\mathrm{DGM}} \frac{\mathrm{C}_{\mathrm{l}}}{\mathrm{~d}_{\mathrm{l}, \mathrm{Kn}}^{\mathrm{e}}} \frac{\mathrm{~B}_{\mathrm{g}}}{\mu} \nabla \mathrm{p} \tag{4.5}
\end{equation*}
$$

Here $\mathrm{d}_{\mathrm{kl}}^{\mathrm{DGM}}$ is DGM diffusion coefficients, which is defined as $d_{\mathrm{kl}}^{\mathrm{DGM}}=\mathrm{H}^{-1}$ and H matrix is defined as

$$
\begin{equation*}
\mathrm{h}_{\mathrm{kl}}=\left(\frac{1}{\mathrm{~d}_{\mathrm{k}, \mathrm{Kn}}^{\mathrm{e}}}+\sum_{\mathrm{j} \neq \mathrm{k}} \frac{\mathrm{X}_{\mathrm{j}}}{\mathrm{D}_{\mathrm{kj}}^{\mathrm{e}}}\right) \delta_{\mathrm{kl}}+\left(\delta_{\mathrm{kl}}-1\right) \frac{\mathrm{X}_{\mathrm{k}}}{\mathrm{~d}_{\mathrm{kl}}^{\mathrm{e}}} \tag{4.6}
\end{equation*}
$$

The permeability $\mathrm{B}_{\mathrm{g}}$ is calculated using Kozeny - Carman equation

$$
\begin{equation*}
\mathrm{B}_{\mathrm{g}}=\frac{\epsilon^{2} \mathrm{~d}_{\mathrm{p}}^{2}}{72 \tau(1-\epsilon)^{2}} \tag{4.7}
\end{equation*}
$$

The viscosity and binary diffusion coefficient are calculated using the kinetic theory of gases. The effective diffusion coefficients are defined as

$$
\begin{align*}
\mathrm{d}_{\mathrm{k}, \mathrm{Kn}}^{\mathrm{e}} & =\frac{\epsilon}{\tau} \mathrm{d}_{\mathrm{k}, \mathrm{Kn}},  \tag{4.8}\\
\mathrm{~d}_{\mathrm{kl}}^{\mathrm{e}} & =\frac{\epsilon}{\tau} \mathrm{d}_{\mathrm{kl}} . \tag{4.9}
\end{align*}
$$

While flowing along the channels, the fuel and the oxidant species are transported into the GDL and CL by a combination of molecular and Knudsen diffusion. The species mass fraction $Y_{\mathrm{k}}$ in the electrodes is given by

$$
\begin{equation*}
\frac{\partial\left(\epsilon \rho \mathrm{Y}_{\mathrm{k}}\right)}{\partial \mathrm{t}}=\frac{\partial \mathrm{j}_{\mathrm{k}}}{\partial \mathrm{y}} ; \mathrm{k}=1 \ldots \mathrm{~N}_{\mathrm{g}} \tag{4.10}
\end{equation*}
$$

The total density within the porous electrodes then follows

$$
\begin{equation*}
\frac{\partial(\epsilon \rho)}{\partial \mathrm{t}}=\sum_{\mathrm{k}=1}^{\mathrm{N}_{\mathrm{g}}} \frac{\partial \mathrm{j}_{\mathrm{k}}}{\partial \mathrm{y}} \tag{4.11}
\end{equation*}
$$

The cell voltage is calculated according to

$$
\begin{equation*}
\mathrm{E}_{\mathrm{cell}}=\mathrm{E}_{\mathrm{rev}}-\eta_{\mathrm{a}}(\mathrm{i})-\left|\eta_{\mathrm{c}}(\mathrm{i})\right|-\eta_{\mathrm{ohm}}(\mathrm{i}) \tag{4.12}
\end{equation*}
$$

Where $\mathrm{E}_{\text {rev }}, \eta_{\mathrm{a}}(\mathrm{i}), \eta_{\mathrm{c}}(\mathrm{i})$ and $\eta_{\text {ohm }}(\mathrm{i})$ are reversible potential, anodic overpotential, cathodic overpotential and ohmic overpotential respectively. The reversible potential $\mathrm{E}_{\mathrm{rev}}$ is calculated according to Nernst equation. We assume that the hydrogen electro - oxidation pathway is dominant, and so the reversible cell potential may be computed using the Nernst equation for the hydrogen oxidation reaction is given by

$$
\begin{equation*}
\mathrm{E}_{\mathrm{rev}}=\mathrm{E}^{0}+\frac{\mathrm{RT}}{2 \mathrm{~F}} \ln \left(\frac{\mathrm{p}_{\mathrm{H}_{2}, \mathrm{a}}}{\mathrm{p}_{\mathrm{H}_{2} \mathrm{O}, \mathrm{a}}}\right)+\frac{\mathrm{RT}}{2 \mathrm{~F}} \ln \left(\mathrm{p}_{\mathrm{O}_{2}, \mathrm{c}}^{1 / 2}\right) . \tag{4.13}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathrm{E}^{0}=\frac{1}{2 \mathrm{~F}}\left(\mu_{\mathrm{H}_{2}}^{0}+\frac{1}{2} \mu_{\mathrm{O}_{2}}^{0}-\mu_{\mathrm{H}_{2} \mathrm{O}}^{0}\right) \tag{4.14}
\end{equation*}
$$

is the ideal standard potential and $\mu_{\mathrm{k}}^{0}$ are standard - state chemical potentials. As indicated by the subscripts a and c, the gas phase species partial pressures are evaluated at the anode and cathode interfaces with the dense electrolyte. The current density can be written in a Butler - Volmer form as

$$
\begin{equation*}
\mathrm{i}=\mathrm{i}_{0}\left[\exp \left(\frac{\left(\beta_{\mathrm{a}}+1\right) \mathrm{F} \eta_{\mathrm{a}}}{\mathrm{RT}}\right)-\exp \left(-\frac{\left(\beta_{\mathrm{c}} \mathrm{~F} \eta_{\mathrm{a}}\right)}{\mathrm{RT}}\right)\right] \tag{4.15}
\end{equation*}
$$

Where, $\eta_{\mathrm{a}}=\mathrm{E}_{\mathrm{a}}-\mathrm{E}_{\mathrm{a}}^{\mathrm{eq}}$ is the activation overpotential and the exchange current density is given as

$$
\begin{gather*}
\mathrm{i}_{0}=\mathrm{i}_{\mathrm{H}_{2}}^{*} \frac{\left(\mathrm{p}_{\mathrm{H}_{2}} / \mathrm{p}_{\mathrm{H}_{2}}^{*}\right)^{1 / 4}\left(\mathrm{p}_{\mathrm{H}_{2} \mathrm{O}}\right)^{3 / 4}}{1+\left(\mathrm{p}_{\mathrm{H}_{2}} / \mathrm{p}_{\mathrm{H}_{2}}^{*}\right)^{1 / 2}}  \tag{4.16}\\
\mathrm{i}=\mathrm{i}_{0}\left[\exp \left(\frac{\left(\beta_{\mathrm{a}}+1\right) \mathrm{F} \eta_{\mathrm{c}}}{\mathrm{RT}}\right)-\exp \left(-\frac{\left(\beta_{\mathrm{c}} \mathrm{~F} \eta_{\mathrm{c}}\right)}{\mathrm{RT}}\right)\right]  \tag{4.17}\\
\mathrm{i}_{0}=\mathrm{i}_{\mathrm{O}_{2}}^{*} \frac{\left(\mathrm{p}_{\mathrm{O}_{2}} / \mathrm{p}_{\mathrm{O}_{2}}^{*}\right)^{1 / 4}}{1+\left(\mathrm{p}_{\mathrm{O}_{2}} / \mathrm{p}_{\mathrm{O}_{2}}^{*}\right)^{1 / 2}} \tag{4.18}
\end{gather*}
$$

## Chapter 5

## Results and Discussion

The fuel cell stack is simulated at different temperatures, different operating potentials and different mole fractions of $\mathrm{CH}_{4}$. Exergy anlaysis of SOFC will be discussed first. The results of efficiency at constant flow rate will then be presented to validate the exergy analysis. Finally efficiency at constant stoichiometry will be discussed.

### 5.1 Exergy efficiency

Fuel cells convert chemical energy in the fuel into the electrical output through electro-chemical reaction along with products. In order to determine the exergy efficiency we need to calculate the exergy of reactants as well as products. The exergy efficiency of the fuel cell is given by [12]

$$
\begin{equation*}
\varepsilon=\frac{\mathbf{P}}{\mathbf{E}_{\mathbf{R}}-\mathbf{E}_{\mathbf{P}}} \tag{5.1}
\end{equation*}
$$

Where $\mathbf{P}, \mathbf{E}_{\mathbf{R}}$ and $\mathbf{E}_{\mathbf{P}}$ are power extracted from the fuel cell, exergy of reactants and exergy of products respectively. The exergy of reactants and products are calculated using Eq. 2.19 and Eq. 2.24 .

Variation of power $(\mathbf{P})$, exergy of reactants $\left(\mathbf{E}_{\mathbf{R}}\right)$ and exergy of products $\left(\mathbf{E}_{\mathbf{P}}\right)$ with operating voltage (V) is shown in Fig. 5.1.

Figure 5.1: Exergy and Power distribution

Even though it is plotted at $800^{\circ} \mathrm{C}$ and $\mathrm{CH}_{4}$ mole fraction of 0.3 in the fuel, the general trend is same at every temperature and for every mole fraction of $\mathrm{CH}_{4}$. From the Figure 5.1, it is clear that power produced reaches maximum and then decreases as the operating voltage increases. On the other hand, exergy of products increases continuously with operating voltage due to two factors: Increase of mole fraction of $\mathrm{H}_{2}$ and CO and decrease of mole fraction of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$ with operating voltage as shown in Fig. 5.2 and Fig. 5.3 respectively.

Figure 5.2: Variation of mole fraction of $\mathrm{H}_{2}$ and CO with operating voltage

Figure 5.3: Variation of mole fraction of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$ with operating voltage

The change in mole fraction of species is insignificant upto 0.7 V . After 0.7 V , mole fraction of $\mathrm{H}_{2}$ and CO increases rapidly due to reduction in electro-chemical reaction of $\mathrm{H}_{2}$. This leads to decrease of water formation and hence reduction in mole fraction of $\mathrm{H}_{2} \mathrm{O}$. It is already stated that exergy efficiency is combination of both physical exergy and chemical exergy. The chemical exergies of $\mathrm{H}_{2}$ and CO are almost 25 times that of $\mathrm{H}_{2} \mathrm{O}$. This causes increase of products exergy and exergy efficiency also changes accordingly.

Exergy analysis is done at three different temperatures and three different mole fractions of $\mathrm{CH}_{4}$. The three different temperatures considered at $600^{\circ} \mathrm{C}, 700^{\circ} \mathrm{C}$ and $800^{\circ} \mathrm{C}$ and $0.3,0.5$ and 0.7 mole fractions of $\mathrm{CH}_{4}$.

The exergy efficiency of SOFC at $600^{\circ} \mathrm{C}$ is shown in Fig. 5.4.

Figure 5.4: Variation of exergy efficiency with mole fraction of $\mathrm{CH}_{4}$ at $600^{\circ} \mathrm{C}$

From the Figure 5.4 it is clear that exergy efficiency decreases with mole fraction of $\mathrm{CH}_{4}$ and shows maximum at 0.3 mole fraction of $\mathrm{CH}_{4}$. From Table 2.2, it is clear that standard chemical exergy of $\mathrm{CH}_{4}$ is more than that of $\mathrm{H}_{2} \mathrm{O}$. Because of this as the mole fraction of $\mathrm{CH}_{4}$ increases, exergy of reactants increases which leads to reduction in exergy efficiency at higher mole fractions of $\mathrm{CH}_{4}$.
Exergy analysis is also done at $700^{\circ} \mathrm{C}$ and $800^{\circ} \mathrm{C}$. The performance of SOFC can be greatly improved at higher temperatures. As the temperature increases exergy of reactants and products increases due to increase in physical and chemical exergy. Also at high temperature reaction kinetics will be improved which leads to increase of power.

The exergy efficiency of SOFC at $700^{\circ} \mathrm{C}$ and $800^{\circ} \mathrm{C}$ are shown in Fig. 5.5 and Fig. 5.6 respectively.

Figure 5.5: Variation of exergy efficiency with mole fraction of $\mathrm{CH}_{4}$ at $700^{\circ} \mathrm{C}$

Figure 5.6: Variation of exergy efficiency with mole fraction of $\mathrm{CH}_{4}$ at $800^{\circ} \mathrm{C}$

The exergy efficiency is maximum at $800^{\circ} \mathrm{C}$ due to above mentioned reasons. The variation of exergy efficiency at different temperatures at 0.3 mole fraction of $\mathrm{CH}_{4}$ is shown in Fig. 5.7.

Figure 5.7: Variation of exergy efficiency with temperature at 0.3 mole fraction of $\mathrm{CH}_{4}$

From the Figure 5.7 it is clear that the maximum exergy efficiency can be obtained at 0.3 mole fraction of $\mathrm{CH}_{4}$ in the range of 0.7 V to 0.8 V .

### 5.2 Efficiency at constant flow rate

Fuel cell is run at different temperatures in constant flow rate condition to determine the efficincy of the fuel cell. To do this, the mole fraction of $\mathrm{CH}_{4}$ is varied from 0.3 to 0.7 at 0.2 increment with the operating voltage.

The fuel inlet molar flow rate is kept constant at $3.36 \mathrm{E}-08 \mathrm{~mol} / \mathrm{s}$ and the air molar flow rate is kept constant at $3.23 \mathrm{E}-06 \mathrm{~mol} / \mathrm{s}$. At 873 K , the velocity of fuel is adjusted to $24.4 \mathrm{~cm} / \mathrm{s}$ and the velocity of air inlet is adjusted to $812.78 \mathrm{~cm} / \mathrm{s}$ to match with the total molar flow rates at fuel inlet and air inlet respectively. At 973 K , the velocity of fuel is adjusted to $27.2 \mathrm{~cm} / \mathrm{s}$ and the velocity of air is adjusted to $906.0 \mathrm{~cm} / \mathrm{s}$. Similarly, at 1073 K , the velocity of fuel and air are adjusted to $30.0 \mathrm{~cm} / \mathrm{s}$ and $998.96 \mathrm{~cm} / \mathrm{s}$ respectively. The velocities of fuel and air at different temperatures are shown in Table.5.1. below.

Table 5.1: Velocities at different temperatures

| S.No | Temperature (K) | Fuel Velocity $(\mathrm{cm} / \mathrm{s})$ | Air Velocity $(\mathrm{cm} / \mathrm{s})$ |
| :--- | :--- | :--- | :--- |
| 1. | 873 | 24.4 | 812.78 |
| 2. | 973 | 27.2 | 906.0 |
| 3. | 1073 | 30.0 | 998.96 |

At constant flow rate condition, the fuel cell efficiency is given as

$$
\begin{equation*}
\eta=\left(\mathrm{E}_{\text {thermo }}\right)\left(\mathrm{E}_{\text {voltage }}\right)\left(\mathrm{E}_{\text {fuel }}\right) . \tag{5.2}
\end{equation*}
$$

Where $\mathrm{E}_{\text {thermo }}, \mathrm{E}_{\text {voltage }}$ and $\mathrm{E}_{\text {fuel }}$ are is reversible thermodynamic efficiency of fuel cell, voltage efficiency of fuel cell and fuel utilization efficiency of fuel cell.

$$
\begin{align*}
& \mathrm{E}_{\text {thermo }}=\frac{\Delta \mathrm{G}}{\Delta \mathrm{H}}  \tag{5.3}\\
& \mathrm{E}_{\text {voltage }}=\frac{\mathrm{V}}{\mathrm{E}}  \tag{5.4}\\
& \mathrm{E}_{\text {fuel }}=\frac{\mathrm{i} / \mathrm{nF}}{\nu_{\text {fuel }}} \tag{5.5}
\end{align*}
$$

For constant flow rate condition,

$$
\begin{gather*}
\eta=\left[\frac{\Delta \mathrm{G}}{\Delta \mathrm{H}}\right]\left[\frac{\mathrm{V}}{\mathrm{E}}\right]\left[\frac{\mathrm{i} / \mathrm{nF}}{\nu_{\text {fuel }}}\right] .  \tag{5.6}\\
\Delta \mathrm{G}=\mathrm{nFE} \tag{5.7}
\end{gather*}
$$

After substitution of Eq. 5.6 in Eq. 5.5,

$$
\begin{equation*}
\eta=\frac{\mathrm{Vi}}{(\Delta \mathrm{H})\left(\nu_{\text {fuel }}\right)} \tag{5.8}
\end{equation*}
$$

The analysis involves varying the operating voltage by keeping the mole fraction of $\mathrm{CH}_{4}$ as constant. This process is continued for mole fractions of $\mathrm{CH}_{4}$ from 0.3 to 0.7 with an increment of 0.2 .

At every temperature the general trend is the same. As the operating voltage increases, the efficiency increases reaches maximum and then decreases. Also, as the mole fraction of $\mathrm{CH}_{4}$ increases, the efficiency decreases. The reason for this is explained as follows: From the Eq. 5.8, it is clear that as molar flow rate $\left(\nu_{\text {fuel }}\right)$ is constant and the only variables are voltage (V), current and enthalpy of the reaction (Eq. 4.1). As the mole fraction of $\mathrm{CH}_{4}$ increases the enthalpy of the reaction (Eq. 4.1) increases as shown in the Table 5.2. Therefore as the mole fraction of the $\mathrm{CH}_{4}$ increases the efficiency decreases as shown in Fig. 5.1-5.3 at $600^{\circ} \mathrm{C}, 700^{\circ} \mathrm{C}$ and $800^{\circ} \mathrm{C}$ respectively.

Table 5.2: Enthalpy change at different mole fractions

|  |  | Enthalpy change $(\mathrm{kJ} / \mathrm{mol})$ |  |  |
| :--- | :--- | :--- | :--- | :--- |
| S.No. | Mole fraction of $\mathrm{CH}_{4}$ | $600^{0} \mathrm{C}$ | $700^{\circ} \mathrm{C}$ | $800^{\circ} \mathrm{C}$ |
| 1. | 0.3 | -240.168 | -240.322 | -240.524 |
| 2. | 0.5 | -400.28 | -400.537 | -400.874 |
| 3. | 0.7 | -560.391 | -560.751 | -561.224 |

Figure 5.8: Efficiency at constant flow rate at $600^{\circ} \mathrm{C}$

Figure 5.9: Efficiency at constant flow rate at $700^{\circ} \mathrm{C}$

Figure 5.10: Efficiency at constant flow rate at $800^{\circ} \mathrm{C}$

As the mole fraction of $\mathrm{CH}_{4}$ increases the fuel cell efficiency decreases due to above mentioned reason. This can be proved by observing the trend of fuel utilization efficiency within the cell. As the mole fraction of $\mathrm{CH}_{4}$ increases fuel cell utilization decreases as shown in Fig. 5.11-5.13 at $600^{\circ} \mathrm{C}, 700^{\circ} \mathrm{C}$ and $800^{\circ} \mathrm{C}$ respectively. Due to fuel utilization efficiency is a part of fuel cell efficiency, decrease in utilization efficiency leads to decrease in fuel cell efficiency. Fuel utilization is a function of operating cell voltage for given fuel stream. At low cell potential, the fuel can be utilized fully and fuel-cell efficiency is a liner function of operating voltage. The efficiency reaches a maximum at an operating potential of 0.7 V to 0.8 V . At low cell voltage, the efficiency increases linearly. In this region the fractional fuel utilization is nearly 1 . At around 0.7 V the utilization begins to fall, contributing to a decreasing efficiency. The utilization efficiency decreases due to fact that the operating voltage exceeds the revesible voltage of the partially depleted fuel stream. At high voltage, utilization decreases to zero due to none of the fuel can be electrochemically oxidized [19].

Figure 5.11: Variation of fuel utilization at different mole fractions of $\mathrm{CH}_{4}$ at $600^{\circ} \mathrm{C}$

Figure 5.12: Variation of fuel utilization at different mole fractions of $\mathrm{CH}_{4}$ at $700^{\circ} \mathrm{C}$

Figure 5.13: Variation of fuel utilization at different mole fractions of $\mathrm{CH}_{4}$ at $800^{\circ} \mathrm{C}$

At constant flow rate condition, the maximum efficiency can be achieved at 0.3 mole fraction of $\mathrm{CH}_{4}$. So mole fraction of $\mathrm{CH}_{4}$ is taken as the reference to compare the efficiency at different temperatures. Here mole fraction of $\mathrm{CH}_{4}$ is kept constant at 0.3 and efficiency trend is compared at $600^{\circ} \mathrm{C}, 700^{\circ} \mathrm{C}$ and $800^{\circ} \mathrm{C}$ as shown in Fig. 5.14. It can be noted that the efficiency is improved as the temperature is increased. The reason for this trend is as follows: Again referring to the Eq. 5.8, it is cleared that molar flow rate is constant and enthalpy change is insignificant (Table 5.2). The variables are voltage and current density. As the temperature is increased, it improves the kinetics of the reaction which results in increase of power. So the highest efficiency can be obtained at 1073K.

Figure 5.14: Efficiency at constant flow rate at different temperatures

### 5.3 Efficiency at constant stoichiometry

Fuel cell can be operated in either a constant flow rate condition or a constant stoichiometry condition. In constant stoichiometry condition, supply of fuel to the fuel cell is adjusted to the current such that fuel cell is always supplied with a bit more fuel than it needs. For this work fuel cell is supplied with 1.2 times more fuel than would be required for 100 percent fuel utilization. In constant stoichiometry condition, fuel utilization is independent of current and fuel utilization efficiency is given by

$$
\begin{equation*}
\mathrm{E}_{\text {fuel }}=\frac{1}{\lambda} \tag{5.9}
\end{equation*}
$$

Where $\lambda$ is stoichiometric factor.

After substituting Eq. 5.9 into Eq. 5.2,

For constant stoichiometry condition,

$$
\begin{equation*}
\eta=\left[\frac{\Delta \mathrm{G}}{\Delta \mathrm{H}}\right]\left[\frac{\mathrm{V}}{\mathrm{E}}\right]\left[\frac{1}{\lambda}\right] \tag{5.10}
\end{equation*}
$$

Fuel cell efficiency at constant stoichiometry condition at $800^{\circ} \mathrm{C}$ is shown in Fig. 5.15

Figure 5.15: Efficiency at constant stoichiometry condition at $800^{\circ} \mathrm{C}$

Unlike constant flow rate condition, eficiency is maximum at low current density in constant stoichiometry condition.

## Chapter 6

## Conclusions

Exergy analysis is done on HT - PEMFC to identify the exergy destructions and exergy losses with in the equipments. Most of the exergy losses are identified in equipments like Steam generator, $1^{\text {st }}$ cogeneration, $2^{\text {nd }}$ cogeneration and SMR/WGR cooler. This could help in the improvement of efficiency of the equipments by modify the process path which leads to improved performance of the entire system.

Exergy analysis is done on SOFC at variable operating tempertures, mole fraction of $\mathrm{CH}_{4}$ and cell voltages. Fuel cell is run at different operating voltages keeping the mole fraction of $\mathrm{CH}_{4}$ as constant for a particular temperature. This process is repeated for different mole fractions of $\mathrm{CH}_{4}$. This helped to identify the operating voltage and mole fraction of $\mathrm{CH}_{4}$ of the fuel cell at which the exergy efficiency is maximum. It is found that operating the fuel cell between 0.7 to 0.8 V and 0.3 mole fraction of $\mathrm{CH}_{4}$ gives the best performance. Also fuel cell is run at different temperatures to determine the performance of it. It is found that as the temperature is increased, the performance of fuel cell is increased and the maximum exergy efficiency can be achieved by operating the fuel cell at $800^{\circ} \mathrm{C}$.

In additional to exergy analysis, fuel cell is run at constant flow rate condition to validate the exergy analysis. The analysis of efficiency at constant flow rate condition is in line with exergy analysis.
